

What is Ansible?

Watch later

Tool to automate IT tasks.

What IT tasks?

Why it's good to automate them?

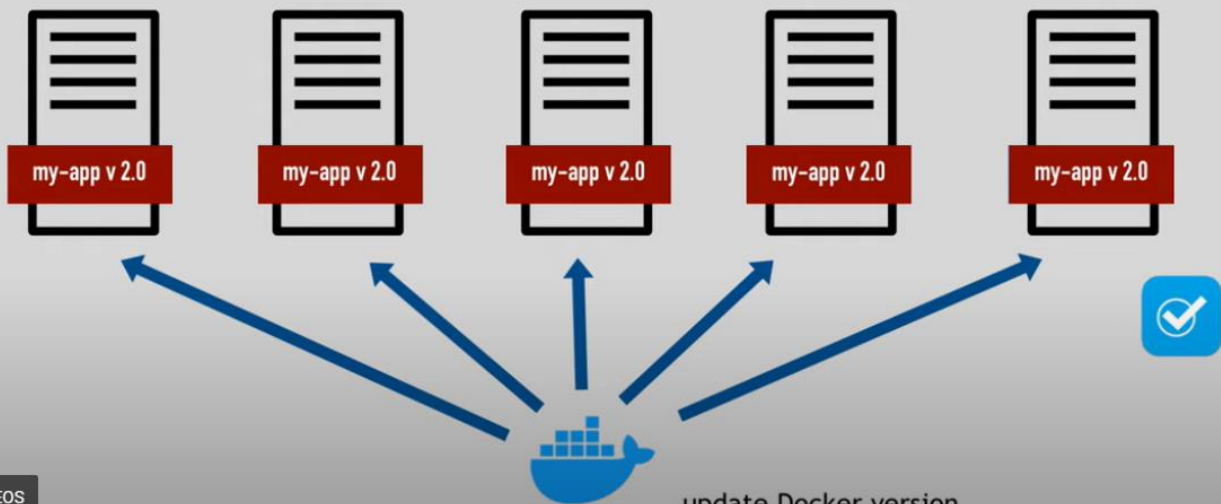

Ansible is a tool that plays an important role in automating the IT tasks.

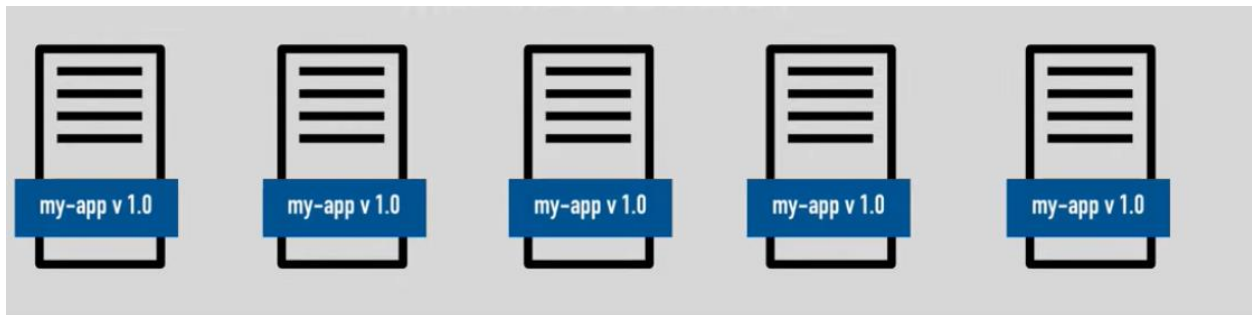

It is important to understand the type of IT tasks that are automated by Ansible and also why it is good to automate them.

Why use Ansible?

Watch later

Share

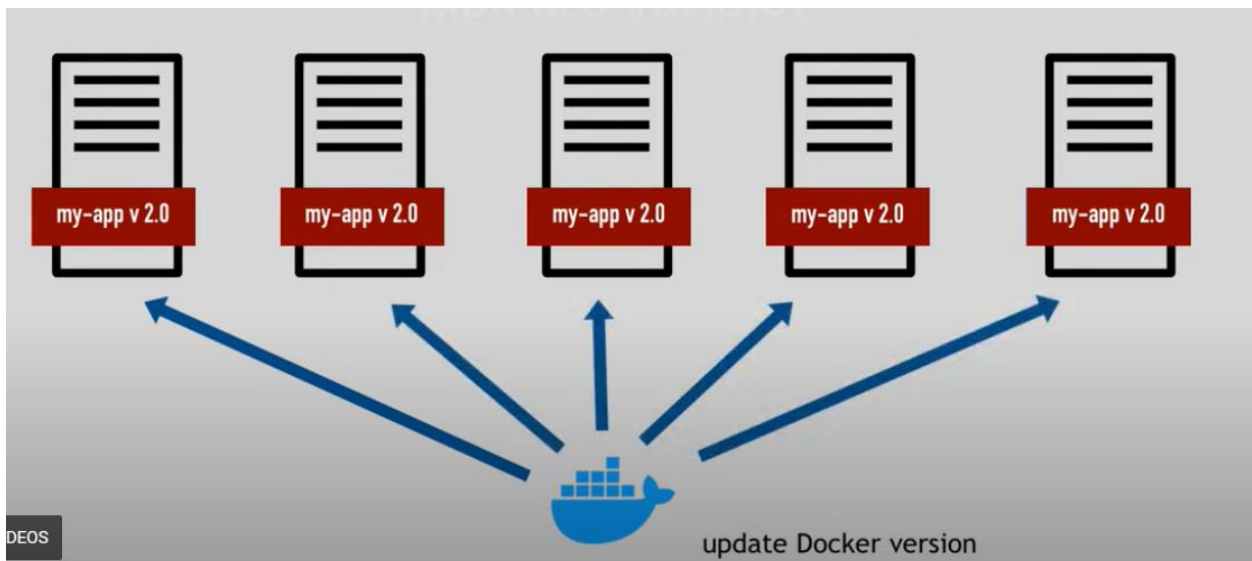

Imagine a scenario where you are running 10 different servers that have application version 1.0 running in all of them.

After six months your company releases another version of the application 2.0 and which must be deployed in all the ten servers.

In addition to deploying the new version of the application 2.0, the manager also wants your team to update the docker version in all the 10 servers.

All these tasks can be automated through the use of ansible, and this is why we say ansible is a configuration, management and deploying tool.

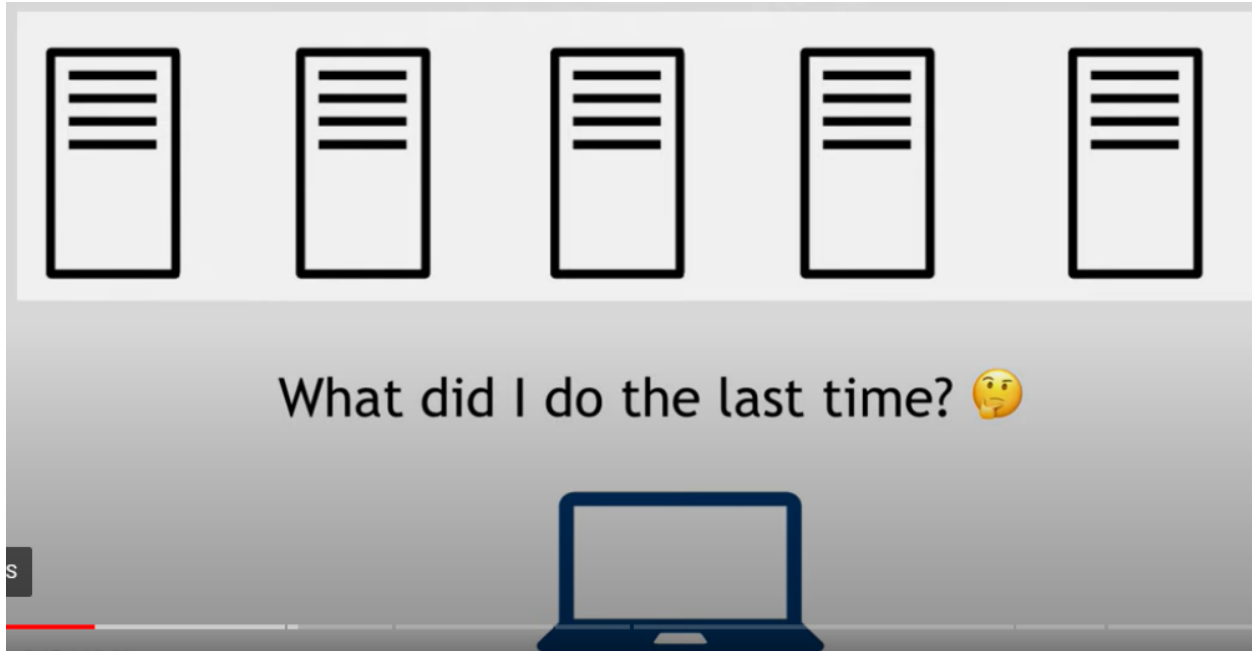

Ansible is also used to carry out all the repetitive tasks in the company.

Updates, backups, system reboots, creating user, creating groups, assigning permission to users and groups

Before ansible came into existence, the whole process of updating the version 2.0 will be done manually.

This means the team will have to ssh to each server through the ansible server and manually deploy the version 2.0 on each of them until they are done with all 10 servers.

It is even more difficult especially when the job involves multiple steps and tasks because you always must remember what you did last time.

One approach that employees used to solve this problem is through taking notes and documenting all the steps and the updates in each server.

They also had to document all the steps used in deploying the updates.

For instance, imagine deploying LAMP stack in 10 centos servers manually. The team must document the following script and must write down all the steps and at the same time document all the updates in each server.

```
#!/bin/sh
```

```
#####  
# Bash script to install an LAMP stack in CentOS  
# Author: Subhash (serverkaka.com)
```

```
# Check if running as root  
if [ "$(id -u)" != "0" ]; then  
    echo "This script must be run as root" 1>&2  
    exit 1  
fi
```

```
# Ask value for mysql root password  
read -p 'db_root_password [secretpasswd]: ' db_root_password
```

echo

```
# prerequisite  
yum install -y wget
```

```
# Install APache  
yum install -y httpd  
systemctl start httpd
```

```
# Set apache autostart at system reboot  
sudo systemctl enable httpd
```

```
# Allow Apache via Firewall  
firewall-cmd --permanent --add-service=http  
systemctl restart firewalld
```

```
# Install PHP  
yum install php php-mysql php-pdo php-gd php-mbstring -y
```

```
# Install MySQL  
# Removing previous mysql server installation  
systemctl stop mysqld.service && yum remove -y mysql-  
community-server && rm -rf /var/lib/mysql && rm -rf  
/var/log/mysqld.log && rm -rf /etc/my.cnf
```

```
# Installing mysql server (community edition)  
yum localinstall -y https://dev.mysql.com/get/mysql57-community-  
release-el7-7.noarch.rpm  
yum install -y mysql-community-server
```

```
# Starting mysql server (first run)  
systemctl enable mysqld.service  
systemctl start mysqld.service  
tempRootDBPass=$(grep 'temporary.*root@localhost'  
/var/log/mysqld.log | tail -n 1 | sed 's/.*root@localhost: //'")
```

```
# Setting up new mysql server root password'  
systemctl stop mysqld.service  
rm -rf /var/lib/mysql/*logfile*
```

```
wget -O /etc/my.cnf "https://my-  
site.com/downloads/mysql/512MB.cnf"  
systemctl start mysqld.service  
mysqladmin -u root --password="$tempRootDBPass" password  
"$db_root_password"  
mysql -u root --password="$db_root_password" -e <<-EOSQL  
    DELETE FROM mysql.user WHERE User="";  
    DROP DATABASE IF EXISTS test;  
    DELETE FROM mysql.db WHERE Db='test' OR Db='test\\_%';  
    DELETE FROM mysql.user where user != 'mysql.sys';  
    CREATE USER 'root'@'%' IDENTIFIED BY  
'${mysqlRootPass}';  
    GRANT ALL ON *.* TO 'root'@'%' WITH GRANT OPTION;  
    FLUSH PRIVILEGES;  
EOSQL  
systemctl status mysqld.service
```

```
# Install PhpMyAdmin  
yum install -y epel-release  
sudo yum -y install phpmyadmin
```

```
# Restart Apache  
systemctl restart httpd
```

echo LAMP server installation completed, you need to configure
PhpMyAdmin for remotely access at
/etc/httpd/conf.d/phpMyAdmin.conf

Ansible can be used to make these processes more efficient and less time consuming.

You can accomplish the same above tasks done manually with ansible using a simple playbook.

Let us look at the same process using Ansible

Lamp Stack

- hosts: localhost

tasks:

- name: Install LAMP stack

become: yes

apt:

pkg:

- apache2

- mysql-client

- php7.2

state: present

update_cache: yes

- name: Start Apache2 Service

become: yes

service:

name: apache2

state: started

enabled: yes

```
- name: Download and Install Composer
shell: |
  php -r "copy('https://getcomposer.org/installer', 'composer-setup.php');"
  sudo php composer-setup.php --install-dir=/usr/local/bin --
filename=composer
  rm composer-setup.php
```

All you need to have is .yaml file and an inventory file [contains the information of the servers to be updated]

In 4 different ways

1

Execute tasks from your own machine

Instead of SSH into all remote servers

2

Configuration/Installation/Deployment steps in a single YAML File

Instead of manual and shell scripts

3

Re-use same file multiple times and for different environments

4

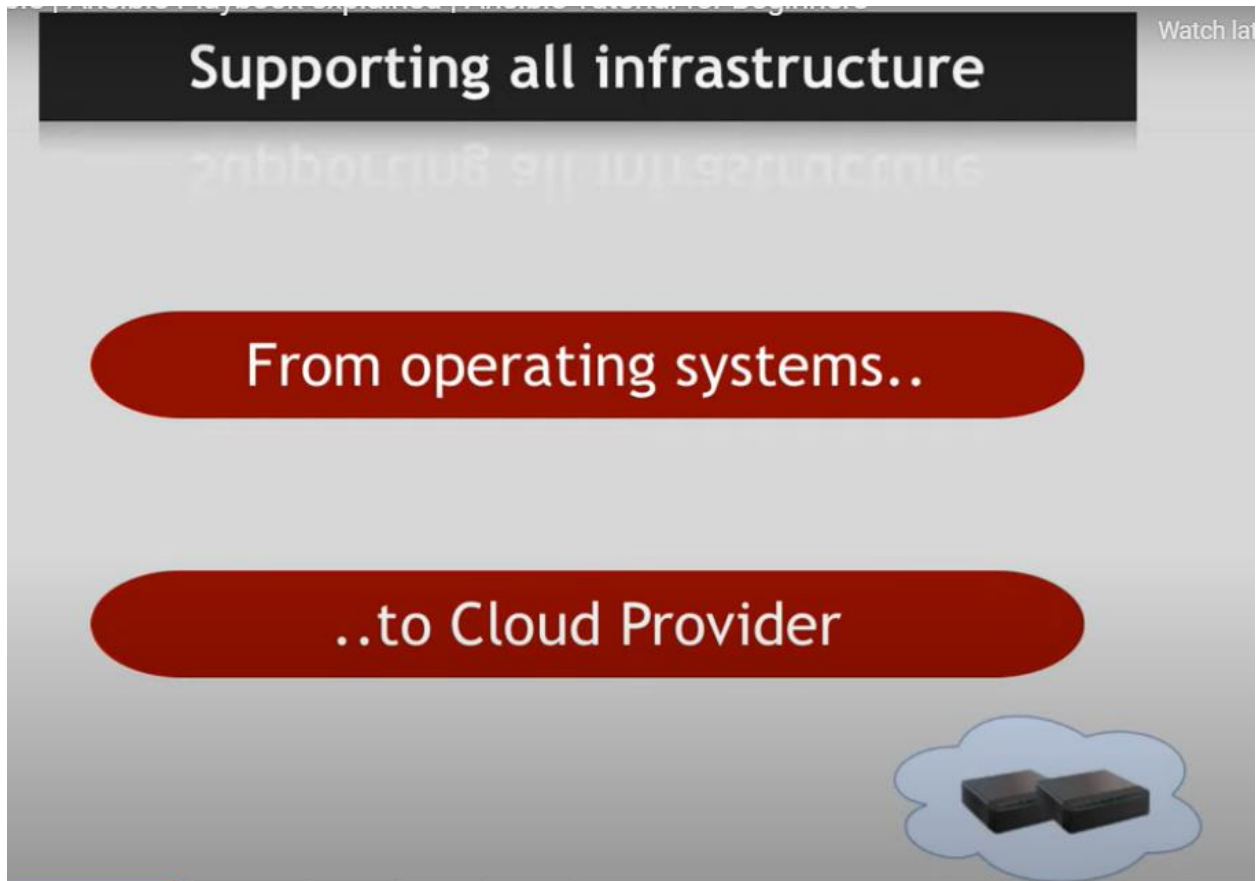

VIDEOS

More reliable and less likely for errors

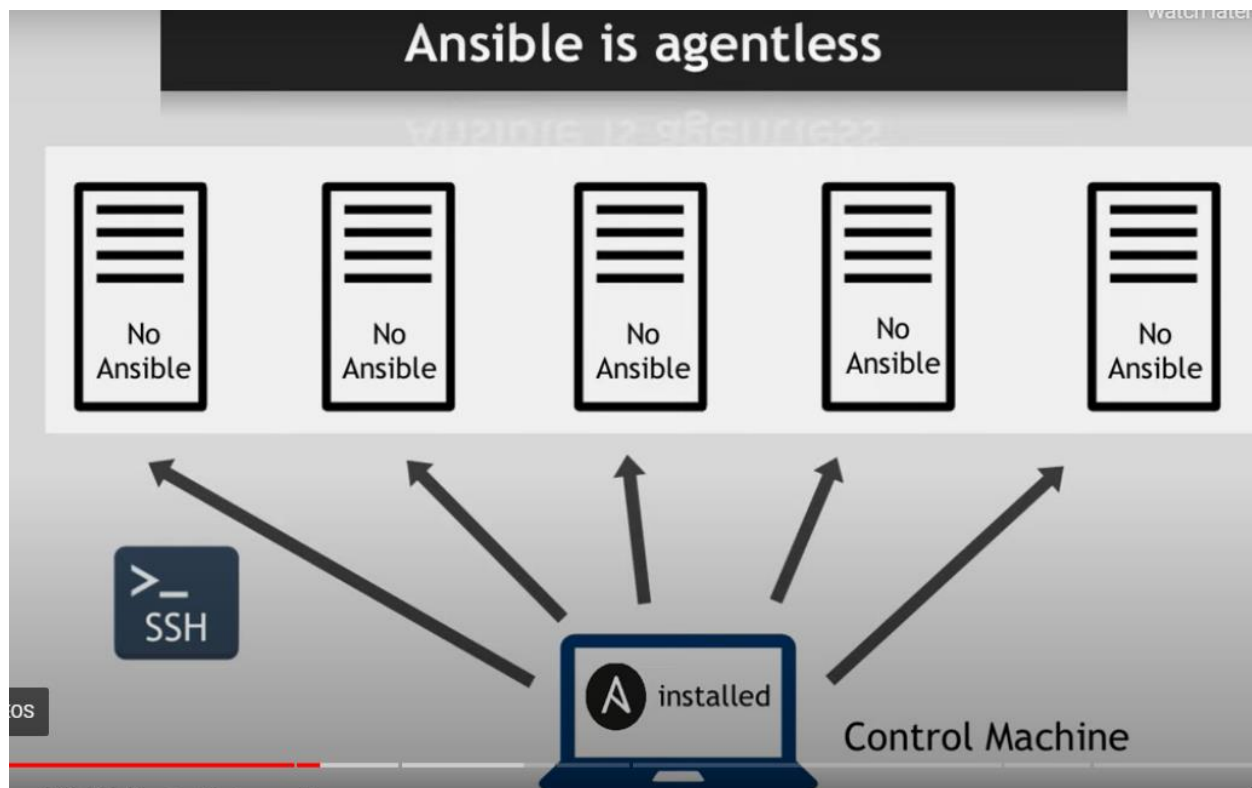

This is important in duplicating the same environment in Dev to production to ensure they both have the same updates and applications which makes the whole Devop Pipeline more efficient because everything run smoothly.

Errors are always going to be present when manually configuring, deploying, and updating the servers.

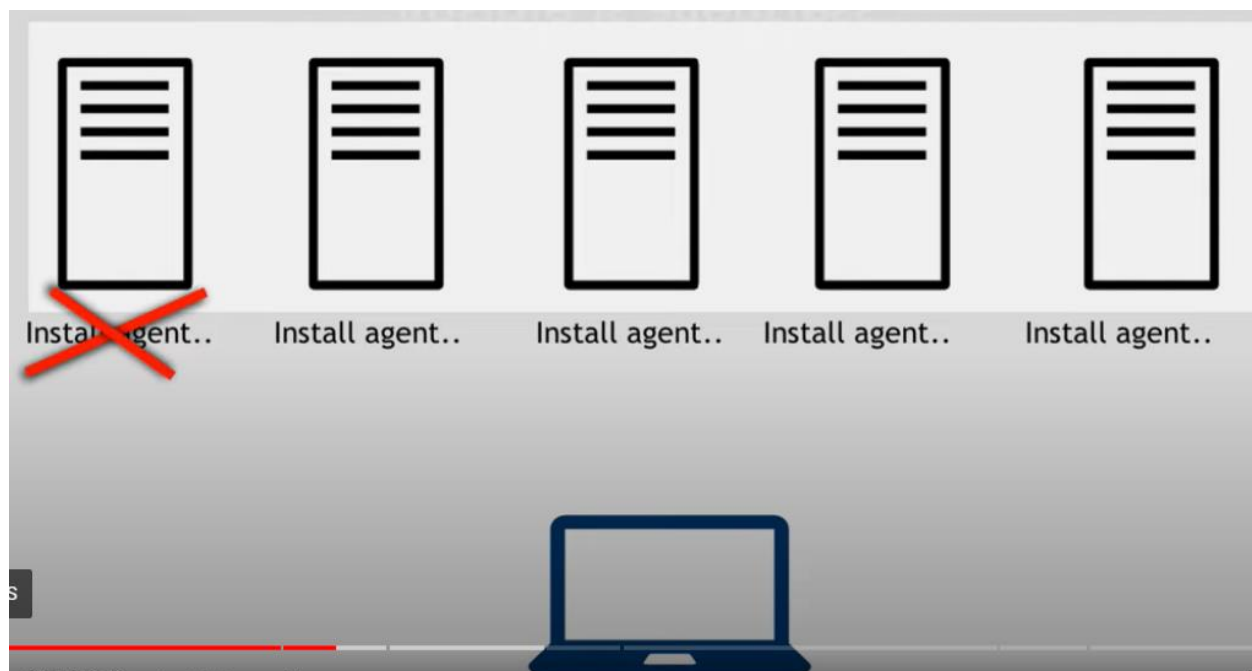

Ansible supports all the infrastructure

You can use ansible to the serves in Premise and in the cloud services such as AWS , Google Cloud, Azure

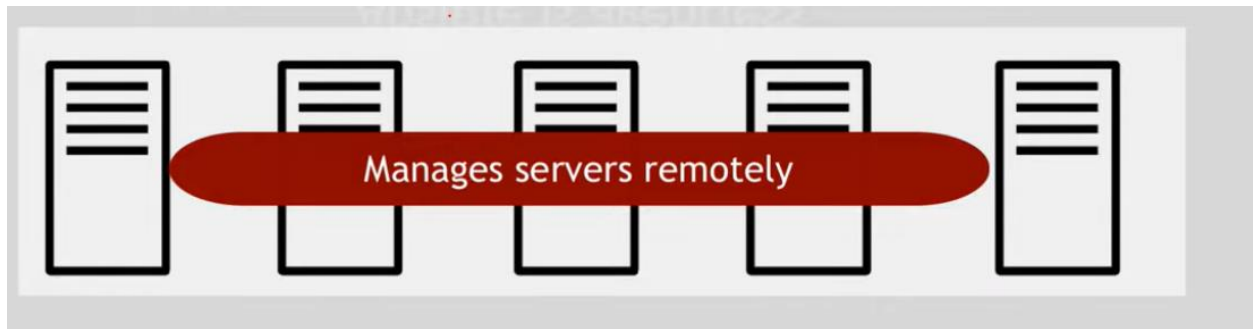

To execute the deployment/configuration file, you just need to simply ssh to the target server from your local machine that has ansible installed/ansible server and the file will be deployed in all the targeted servers.

Ansible is agentless? What does this mean

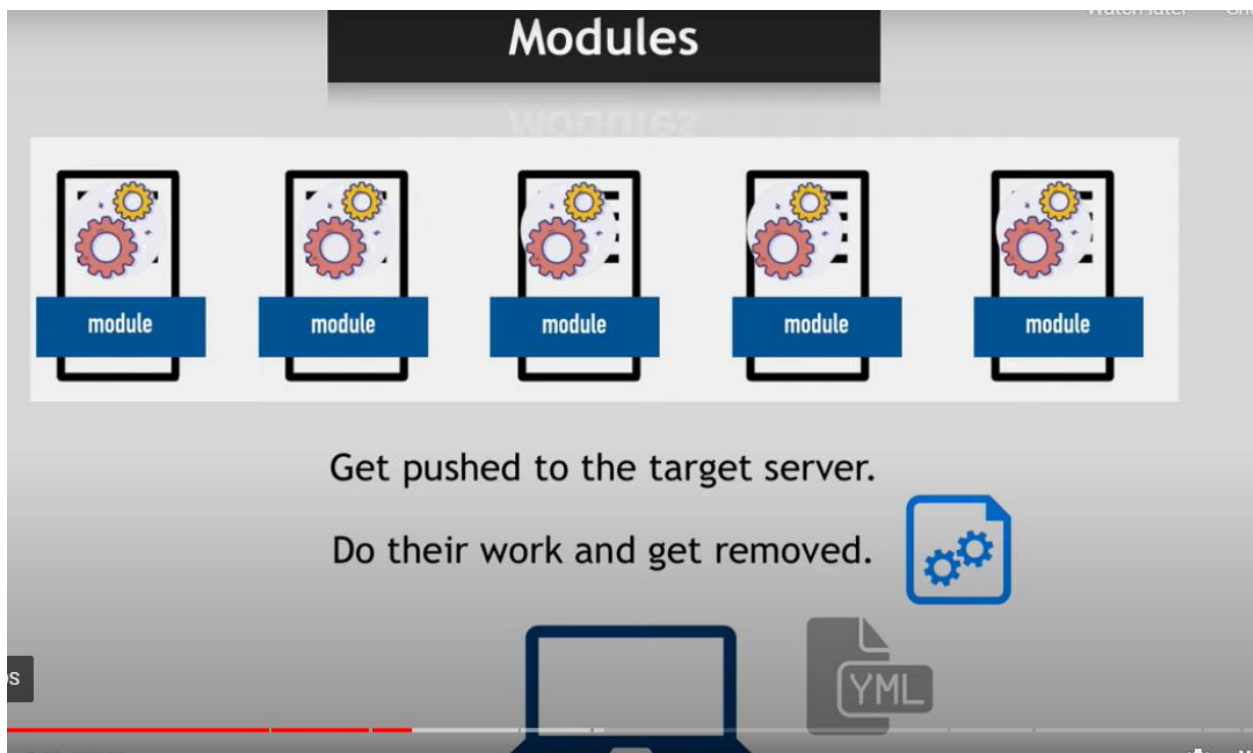

This is the unique characteristic of ansible which is different from other tools. To configure the servers, you always must install the agent for the tool in each server to enhance the process. However, for the ansible, you do not need to have an agent tool for ansible to manage the updates or deploy them into all the servers.

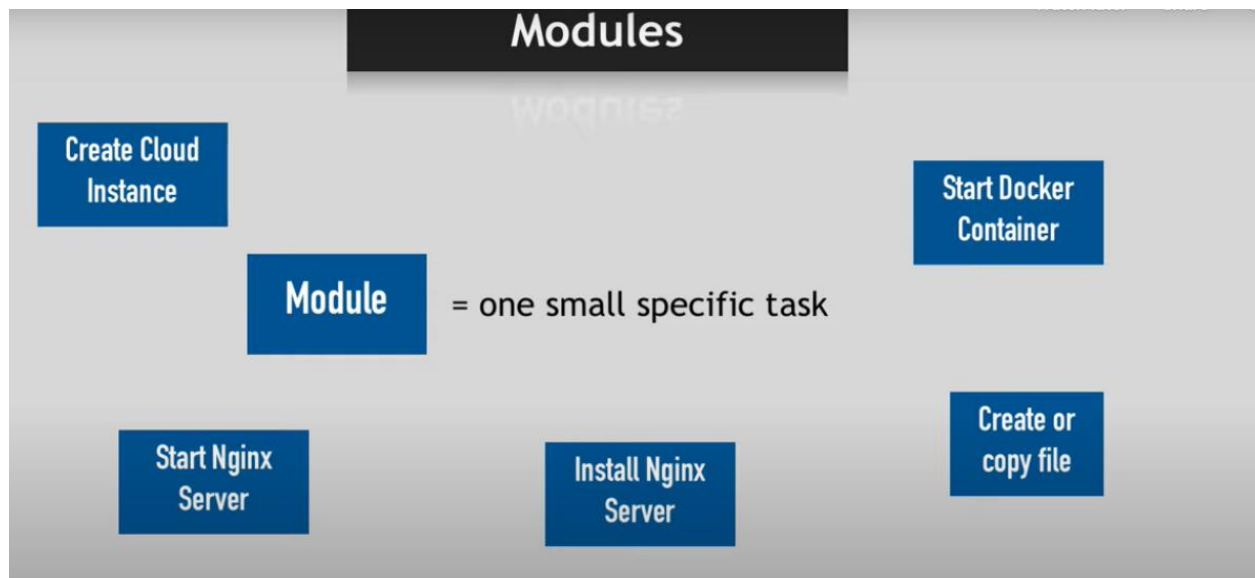

You just need to install the ansible agent in one of the machines, or even your laptop and you can manage the rest of the servers remotely.

or you can use the ansible server to manage all the centos, ubuntu etc servers that need to receive the updates through ssh/remotely.

Ansible works with Modules

Lamp Stack

- hosts: localhost

tasks

- name: Install LAMP stack – module [**small packages to be installed**]

become: yes

apt:

pkg:

- apache2

- mysql-client

- php7.2

state: present

update_cache: yes

- name: Start Apache2 Service

become: yes

service:

name: apache2

state: started

enabled: yes

Ansible uses YAML

Watch

no need for learning a specific language for Ansible

Example Module Usages

This is just like terraform. No need to learn the usage as the usage is given.

Modules are granular and specific

- multiple modules
- in a certain sequence
- grouped together

To execute complex tasks, you can include multiple modules, grouped in a specific way to accomplish a certain configuration.

IP Address: 172.17.0.2 and 172.17.0.3

Ansible Playbooks

```
tasks:
- name: Rename table foo to bar
  postgresql_table:
    table: foo
    rename: bar

- name: Set owner to someuser
  postgresql_table:
    name: foo
    owner: someuser

- name: Truncate table foo
  postgresql_table:
    name: foo
```

1 Task = action to be performed

tasks

1 task = action to be performed

Ansible Playbooks

Execute multiple modules in a sequence:

```
tasks:
- name: create directory for nginx
  file:
    path: /path/to/nginx/dir
    state: directory

- name: install nginx latest version
  yum:
    name: nginx
    state: latest

- name: start nginx
  service:
    name: nginx
```

Module name

Arguments

Where should these tasks execute?

Ansible Playbooks

```
- hosts: databases
  remote_user: root

  tasks:
    - name: Rename table foo to bar
      postgresql_table:
        table: foo
        rename: bar

    - name: Set owner to someuser
      postgresql_table:
        name: foo
        owner: someuser

    - name: Truncate table foo
      postgresql_table:
        name: foo
```

Where should these tasks execute?

HOSTS

This playbook will be executed through the inventory file.

Strict indentation

Ansible Playbooks

```
- hosts: databases
  remote_user: root

  tasks:
    - name: Rename table foo to bar
      postgresql_table:
        table: foo
        rename: bar

    - name: Set owner to someuser
      postgresql_table:
        name: foo
        owner: someuser

    - name: Truncate table foo
      postgresql_table:
        name: foo
```

Where should these tasks execute?

HOSTS

With which user should the tasks execute?

REMOTE_USER

Strict indentation!

Ansible Inventory List

Hosts File

```
10.24.0.100

[webservers]
10.24.0.1
10.24.0.2

[databases]
10.24.0.7
10.24.0.8
```

```
- hosts: databases
  remote_user: root
```

```
hosts: webservers
remote_user: root
```

Inventory = all the machines involved in task executions

Inventory file

No spaces between the square brackets

Let have a playbook and deploy it in two docker containers

ansible --version

```
[root@josh ansible]# ansible --version
ansible 2.9.25
  config file = /etc/ansible/ansible.cfg
  configured module search path = [u'/root/.ansible/plugins/modules', u'/usr/share/ansible/plugins/modules']
  ansible python module location = /usr/lib/python2.7/site-packages/ansible
  executable location = /usr/bin/ansible
  python version = 2.7.5 (default, Nov 16 2020, 22:23:17) [GCC 4.8.5 20150623 (Red Hat 4.8.5-44)]
[root@josh ansible]#
```

cd /etc/ansible/

ls

```
[root@josh ansible]# cd /etc/ansible/
[root@josh ansible]# ls
advanced-group.yml  ansible.cfg  den-inventory.yml  dev.vars.yml  hosts  pro.vars.yml  qa-inventory.yml  roles  web-deploy.yml
[root@josh ansible]#
```

touch dev.vars.yml

Put this information

[web-server]

```
server1 ansible_host=172.17.0.3 ansible_ssh_user=root ansible_ssh_pass=school1
{ this is hos to mask ip address }
```

[database-server]

```
server2 ansible_host=172.17.0.2 ansible_ssh_user=root ansible_ssh_pass=school1
```

:WQ

Let us now create a playbook

```
#touch web-deploy.yml
```

```
---
```

```
- hosts: webserver-atlanta
```

```
  user: root
```

```
  ignore_errors: yes
```

```
  tasks:
```

```
    - name: ping server
```

```
      ping:
```

```
    - name: check the date
```

```
      command: date
```

```
    - name: Run linux command
```

```
      shell: pwd
```

```
    - name: Install mysql
```

```
      yum: name=mysql state=present
```

```
- hosts: webserver
```

```
  become: yes
```

tasks:

- name: Setup repo for Mysql 5.7

yum:

name: <http://repo.mysql.com/mysql57-community-release-el7-10.noarch.rpm>

state: present

- name: Install Packages

yum:

name:

- httpd

- mysql-community-server

- firewalld

state: present

- name: Start Apache

service:

name: httpd

state: started

enabled: yes

- name: Start Mysql

service:

name: mysqld

state: started

enabled: yes

- name: Start Firewalld

service:

name: firewalld

state: started

enabled: yes

- name: Apache to listen on 8080

lineinfile:

path: /etc/httpd/conf/httpd.conf

regexp: Listen 80

line: Listen 8080

notify: Restart Apache

- name: Allow 8080 port

firewalld:

port: 8080/tcp

permanent: yes

state: enabled

notify: Restart Firewalld

- name: Disable SELinux

selinux:

state: disabled

handlers:

- name: Restart Firewalld

service:

- name: firewalld

- state: restarted

- name: Restart Apache

service:

- name: httpd

- state: restarted

Important commands

```
# ansible webserver-atlanta -m ping -i dev.vars.yml
```

A green ping pong message should appear

With playbook

Checking the status

```
Ansible-playbook web-deploy.yml -I dev.vars.yml --syntax-check
```

Execute the play-book

```
Ansible-playbook web-deploy.yml -I dev.vars.yml
```
